

# Wakefield Accelerator

**Process:** Laser radiation pressure displaces electrons  
Space charge causes oscillating density 'wake' moving with the laser  
Wake electric fields of  $\sim$ GV/cm accelerate particles

Analogy: boat displacing water

Particle injection

## Motivation: Increase Particle Energies

- Increasing particle energies probe smaller and smaller scales of matter
    - **1910:** Rutherford: scattering of MeV scale alpha particles revealed structure of **atom**
    - **1950ies:** scattering of GeV scale electron revealed finite size of **proton and neutron**
    - **Early 1970ies:** scattering of tens of GeV electrons revealed internal structure of proton/neutron, ie quarks.
  - Increasing energies makes particles of larger and larger mass accessible
    - GeV type masses in 1950ies, 60ies (Antiproton, Omega, hadron resonances...)
    - Up to 10 GeV in 1970ies (J/Psi, Ypsilon...)
    - Up to ~100 GeV since 1980ies (W, Z, top, Higgs...)
  - Discoveries went hand in hand with theoretical understanding of underlying laws of nature
    - **Standard Model** of particle physics
  - Increasing particle energies probe earlier times in the evolution of the universe.
    - Temperatures at early universe were at levels of energies that are achieved by particle accelerators today
    - Understand the origin of the universe
- Large list of unsolved questions!
- **Need particle accelerators with new energy frontier**

# Big questions in particle physics

The Standard Model is amazingly successful, but there are unanswered questions:

- ❖ What are the consequences of the “Higgs” particle discovery?
- ❖ Why is there so much matter (vs. anti-matter) ?
- ❖ Why is there so little matter (5%) in the Universe?
- ❖ Can we unify the forces?

Large Hadron Collider, LHC, 27 km circumference, 7 TeV

# Circular Collider

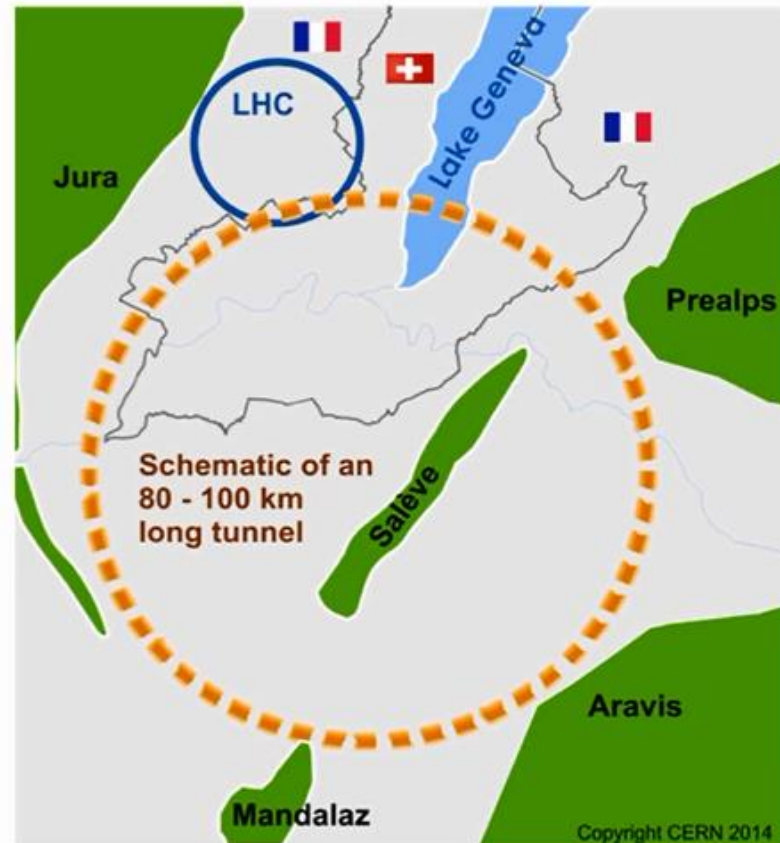

## FCC, Future Circular Collider

80 – 100 km diameter

100 TeV (pp)

>350 GeV ( $e^+e^-$ )

20 T dipoles

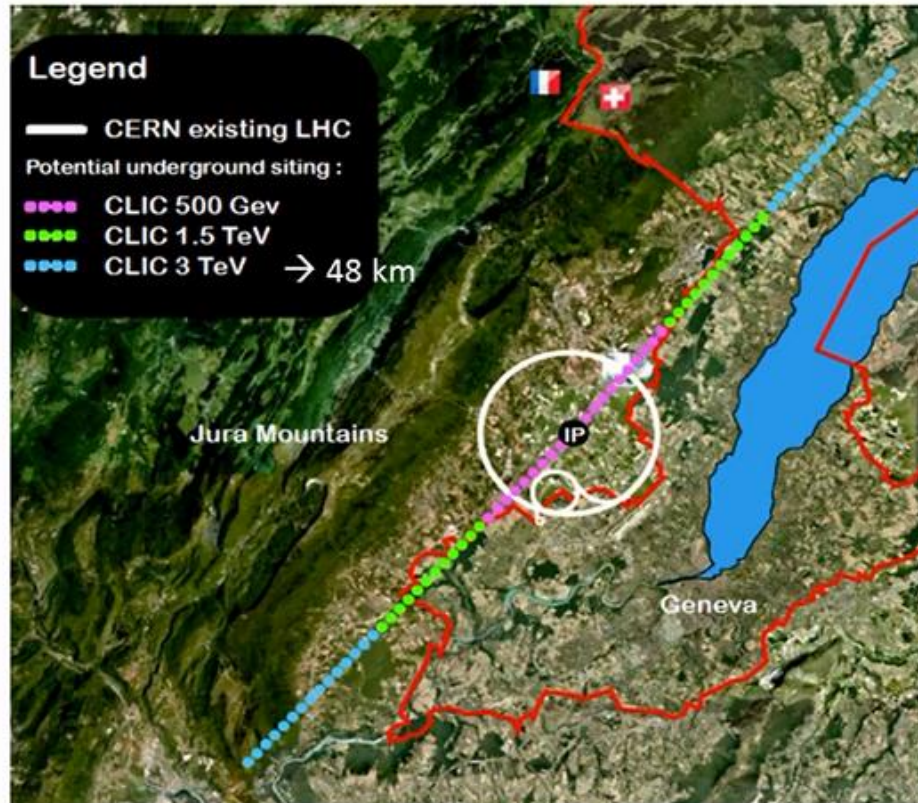

# Linear Colliders

## CLIC

48 km length  
3 TeV ( $e^+e^-$ )

Accelerating elements:  
Cavities: 100 MV/m

# Conventional Accelerating Technology

## Today's RF cavities or microwave technology:

- Very successfully used in all accelerators (hospitals, scientific labs,...) in the last 100 years.
- Typical gradients:
  - LHC: 5 MV/m
  - ILC: 35 MV/m
  - CLIC: 100 MV/m

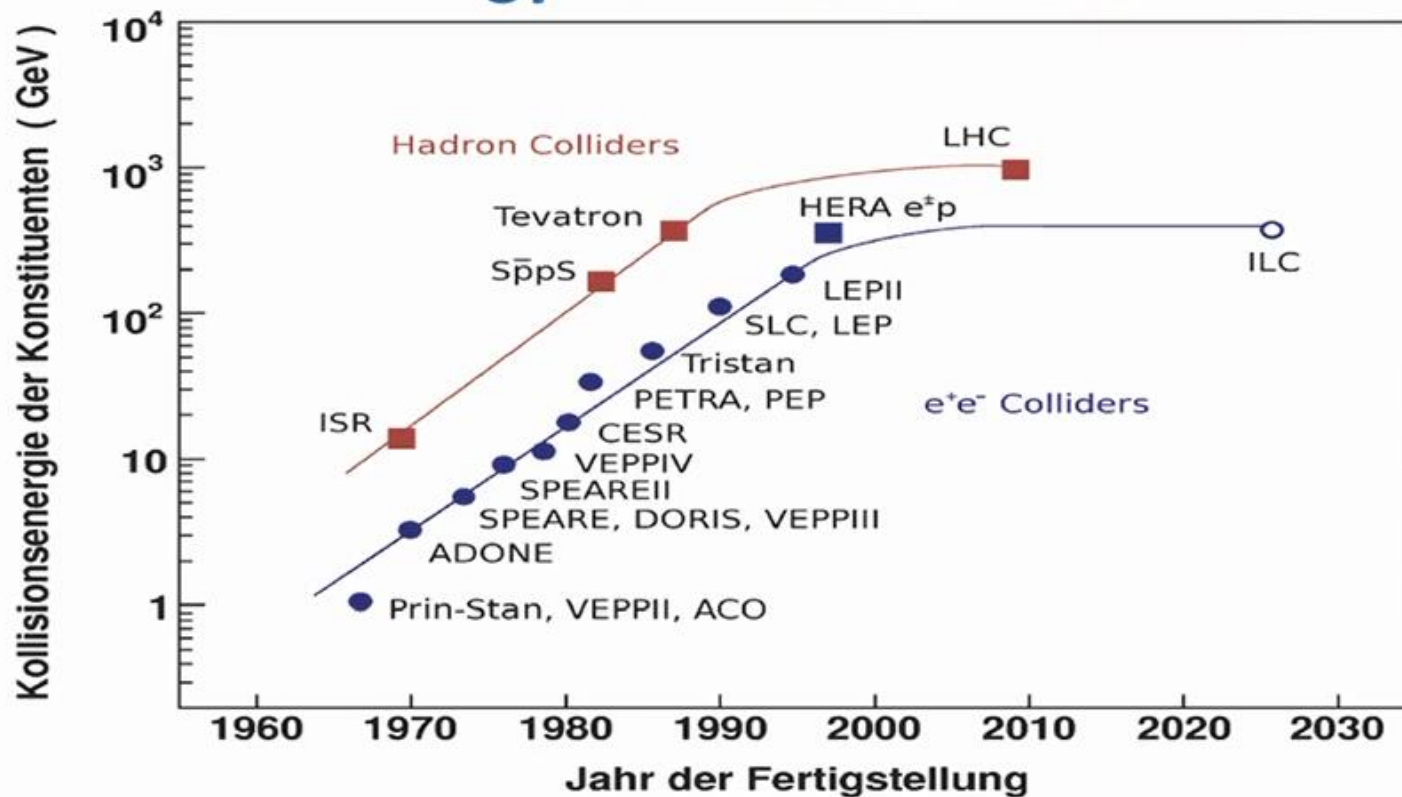

## However:

- accelerating fields are limited to  $<100$  MV/m
  - In metallic structures, a too high field level leads to break down of surfaces, creating discharge.
  - Fields cannot be sustained, structures might be damaged.
- several tens of kilometers for future linear colliders

# Saturation at Energy Frontier for Accelerators

→ Project size and cost increase with energy

*New directions in science* are launched by *new tools* much more often than by *new concepts*.

The effect of a *concept-driven* revolution is to explain old things in new ways.

The effect of a *tool-driven* revolution is to discover new things that have to be explained.

from Freeman Dyson 'Imagined Worlds'

## RF Cavity

**1 m  $\Rightarrow$  50 MeV Gain**

Electric field  $<$  100 MV/m

## Plasma Cavity

**1 mm  $\Rightarrow$  100 MeV**

Electric field  $>$  100 GV/m

Compactness of plasma 'cavity'. Left: Radiofrequency cavity. Right: Non-linear laser plasma wakefield. The laser pulse in yellow propagates from left to right, the iso-electronic density is shown in blue and the electron bunch in red.

# Linear Colliders

## Plasma based Linear Collider

# Let's look at the driver first: a relativistically intense laser pulse

- Peak power **1 PW** or **1,359,621,617,300 PS** (if you are into cars) compare to total nuclear power output in the world **0.000 374 PW**
- Energy  $\sim 10$  J in  $\sim 10$  fs = **0.000 000 000 000 01 s** duration focused to  $\sim 50$   $\mu\text{m}$  spots (size of thin hair)
- $\sim 4 \cdot 10^{19}$  photons
- Intensity  $\sim 10^{19}$   $\text{W}/\text{cm}^2$  electrons become relativistic
- Electric fields of **8.6 TV/m**, magnetic fields of  **$\sim 28954$  Tesla**

**Burning question: can these fields be used for particle acceleration?**

# But interacting the laser with matter works!

- Intensity  $\sim 10^{19} \text{ W/cm}^2$  → light pressure on matter  $\sim 300 \text{ Tbar}$ , electron temperature  $\sim \text{MeV}$  or  $\sim G^\circ\text{C}$ !

# Laser excitation of strong plasma waves

- Intense laser-pulse from left to right
- Pushes away electrons by its light pressure or ponderomotive force (ions are too heavy, hardly move)
- Creates electron-depleted cavity and sets up charge separation
- Strong electrostatic fields pull back electrons on axis
- Electrons oscillate and create copropagating wakefield

# Principle of Plasma Wakefield Acceleration

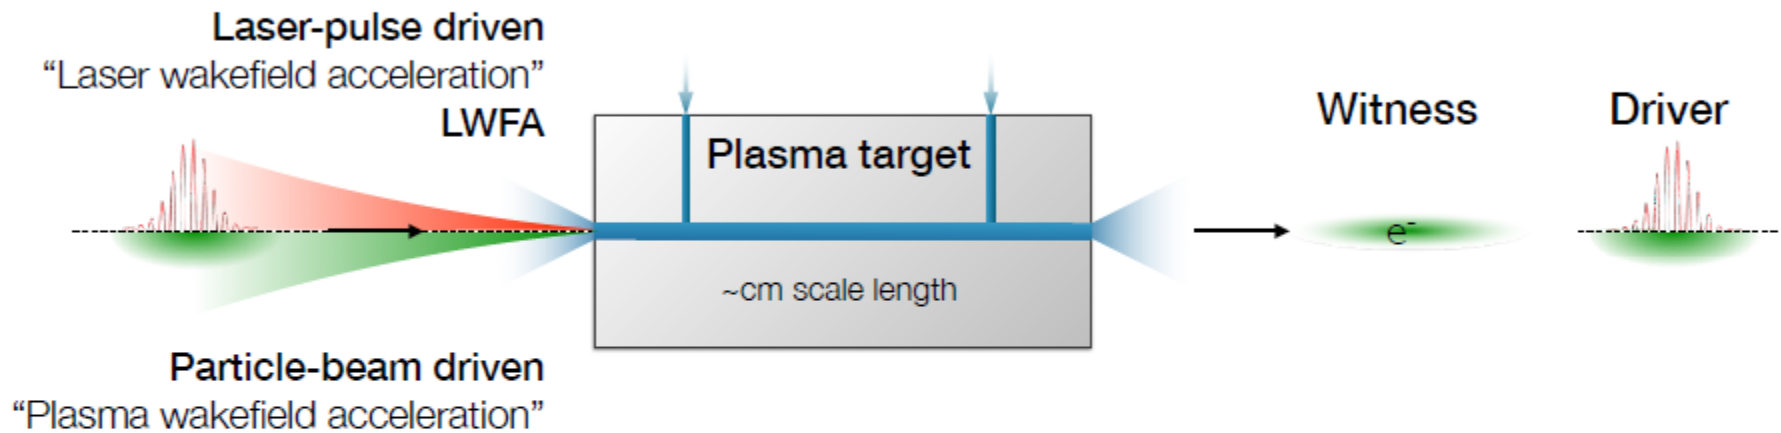

- Laser drive beam
  - Ponderomotive force
- Charged particle drive beam
  - Transverse space charge field
    - Reverses sign for negatively (blow-out) or positively (suck-in) charged beam

use **transverse field** to create a **longitudinal field** for acceleration

- Plasma wave/wake excited by relativistic particle bunch
- Plasma e<sup>-</sup> are expelled by space charge force
- Plasma e<sup>-</sup> rush back on axis
- Acceleration physics identical for LWFA, PWFA

# Plasma wakefield acceleration in a nutshell

## PWFA vs. LWFA

- average power of up to MW (vs. ~100 W)
  - wall-plug efficiency of ~10% (vs. < 0.1%)
- beam-driven wakes (currently) the only viable solution for high-average-power applications

 PWFA

**Size of structure**

$$\lambda_p \approx \frac{2\pi c}{\omega_p} \approx (33 \text{ km}) \sqrt{n_e^{-1} [\text{cm}^{-3}]}$$

typically  $\lambda_p \approx 33 \mu\text{m}$  (for  $n_e \approx 10^{18} \text{ cm}^{-3}$ )

**Electric field strength**

$$E \approx \frac{mc\omega_p}{e} \approx (96 \text{ V/m}) \sqrt{n_e [\text{cm}^{-3}]}$$

typically  $E \approx 100 \text{ GV/m}$  (for  $n_e \approx 10^{18} \text{ cm}^{-3}$ )

# Plasma considerations

Based on linear fluid dynamics:

$$\omega_p = \sqrt{\frac{n_p \cdot e^2}{\epsilon_0 \cdot m_e}}$$

$$\lambda_p \approx 1 [mm] \cdot \sqrt{\frac{10^{15} [cm^{-3}]}{n_p}} \quad \text{or} \quad \approx \sqrt{2} \cdot \pi \cdot \sigma_z$$

$$E \approx 2 [GV m^{-1}] \cdot \left(\frac{N}{10^{10}}\right) \cdot \left(\frac{100 [\mu m]}{\sigma_z}\right)^2$$

Relevant physical quantities:

- Oscillation frequency  $\omega_p$
- Plasma wavelength  $\lambda_p$
- Accelerating gradient E

where

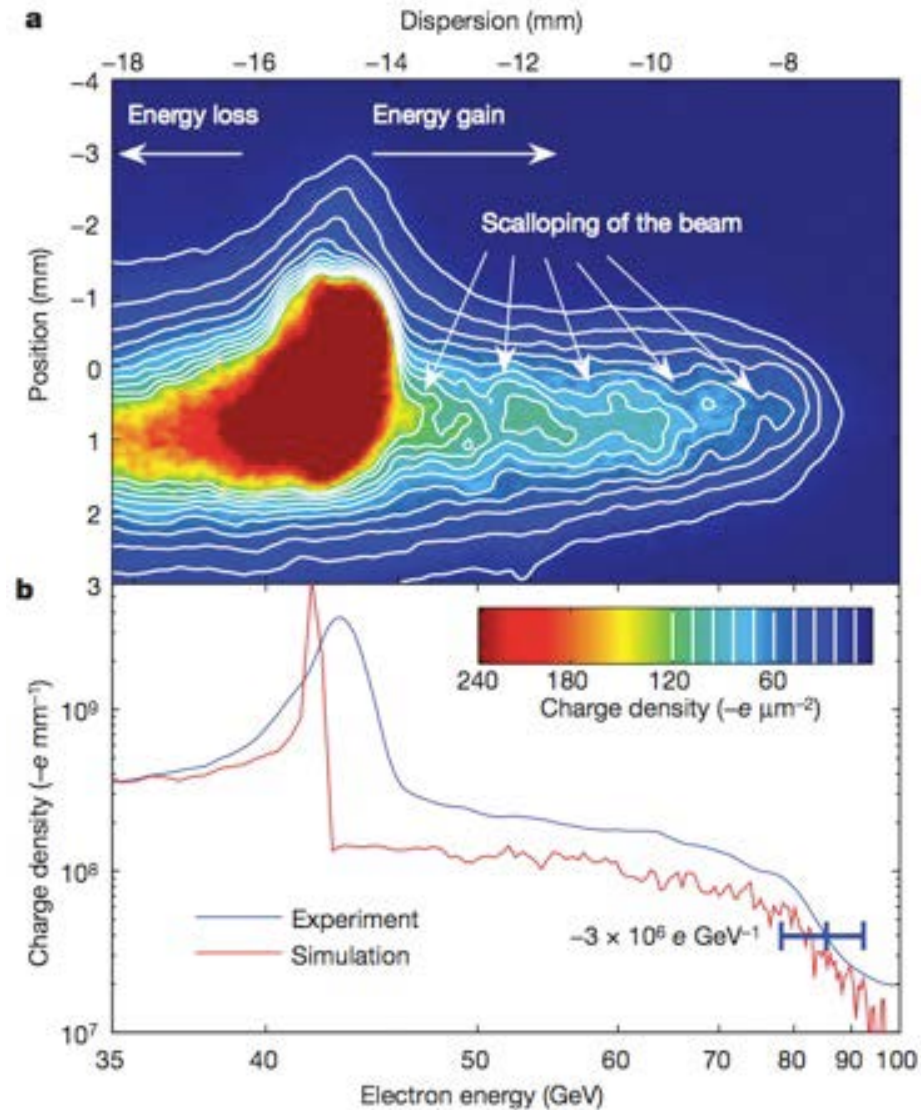

- $n_p$  is the plasma density
- $e$  is the electron charge
- $\epsilon_0$  is the permittivity of free space
- $m_e$  is the mass of electron
- $N$  is the number of drive-beam particles
- $\sigma_z$  is the drive-beam length

High gradients with:

- Short drive beams (and short plasma wavelength)
- Pulses with large number of particles (and high plasma density)

# Plasma wakefield experiments

- ❖ Pioneering work using a LASER to induce wakefield up to 100 GV/m.
- ❖ Experiments at SLAC have used a particle (electron) beam:
  - Initial energy  $E_e = 42 \text{ GeV}$
  - Gradients up to  $\sim 52 \text{ GV/m}$
  - Energy doubled over  $\sim 1 \text{ m}$
  - Next stage FACET project  
<http://facet.slac.stanford.edu>
- ❖ High proton beams of much higher energy:
  - HERA (DESY):  $1 \text{ TeV}$
  - Tevatron (FNAL):  $1 \text{ TeV}$
  - CERN:  $24/450 \text{ GeV}$  and  $3.5 (7) \text{ TeV}$

# Rubidium plasma source

- ❖ Synthetic oil surrounding Rb for temperature stability and hence density uniformity
- ❖ Vacuum tube surrounding oil suppressing heat loss
- ❖ Rubidium vapor sources available commercially; development of fast valves started in collaboration with industry
- ❖ Need  $1 - 2 TW$  laser with  $30 - 100 fs$  pulse

# Experimental setup

1. Merging of SPS proton beam & ionizing/seeding laser pulse
2. Schematic relative timing
3. SMI developing, electron bunch parallel to proton bunch
4. Acceleration sections
5. Laser pulse dumped & diagnosed
6. Electro-optical sampling diagnostic
7. Transition radiation diagnostics
8. RF electron gun
9. e/p bunch merging section
10. Electron spectrometer system

Surfing wakefields to create smaller accelerators

## Building Accelerators Based on PWA

Lasers:  $\sim 40$  J/pulse

Electron drive beam: 30 J/bunch

Proton drive beam: SPS 19kJ/pulse, LHC 300kJ/bunch

- To reach TeV scale with electron/laser driven PWA: need several stages, and challenging wrt to relative timing, tolerances, matching, etc...
  - effective gradient reduced because of long sections between accelerating elements....

- **Proton drivers:** large energy content in proton bunches  $\rightarrow$  interesting for plasma wakefield accelerators  $\rightarrow$  to reach high energies of a witness beam possible in few stages.
- But: need short bunches  $\rightarrow$  self-modulation instability

19

### *Lasers do not have enough energy:*

- Can not propagate long distances in plasma
- Can not accelerate electrons to high energy
- For high energy, need multiple stages

# Plasma wakefield accelerator

## Long beam : self-modulation

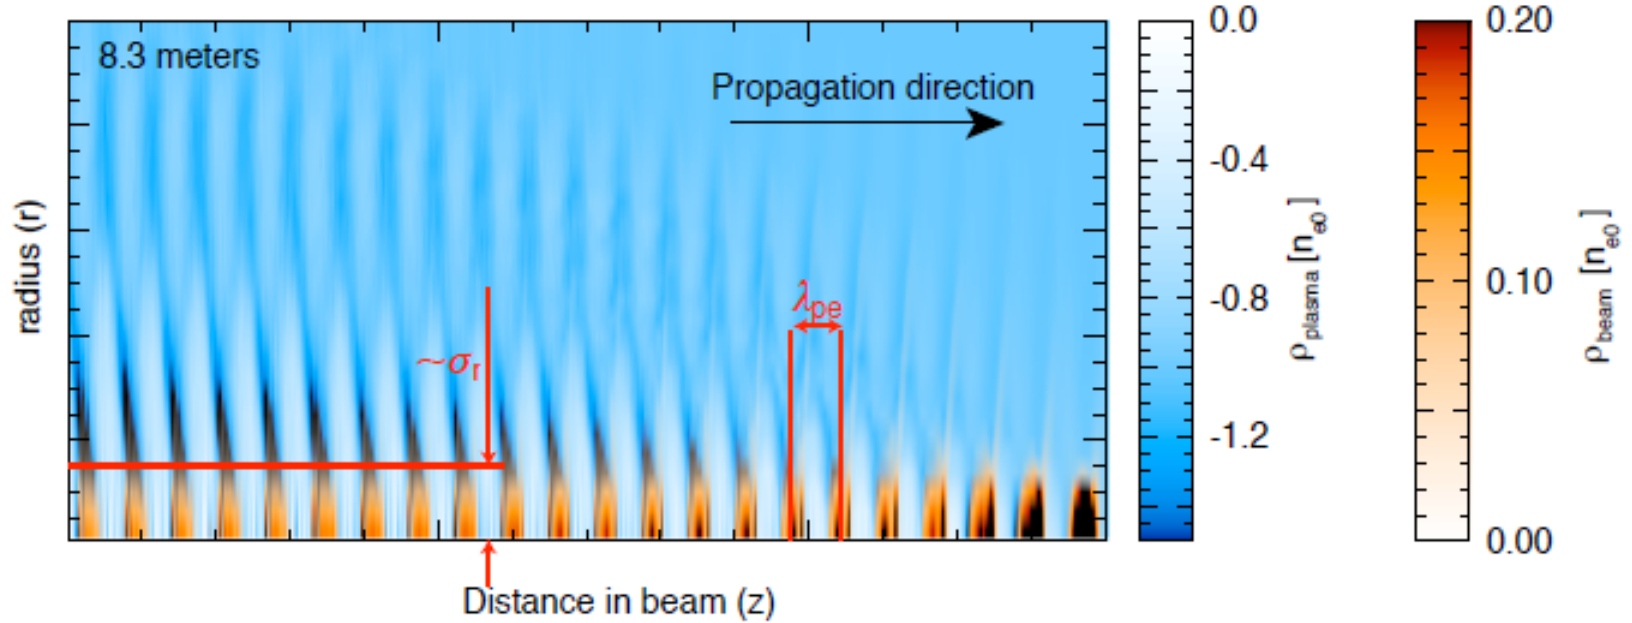

- Microbunches are spaced at the plasma wavelength and act constructively to generate a strong plasma wake.
- Seeding the modulation is critical. Use laser pulse (or short electron beam).

Thanks to J. Holloway (UCL)

Self-modulated driver beam

# Self-modulation of the proton beam

## CERN SPS proton beam

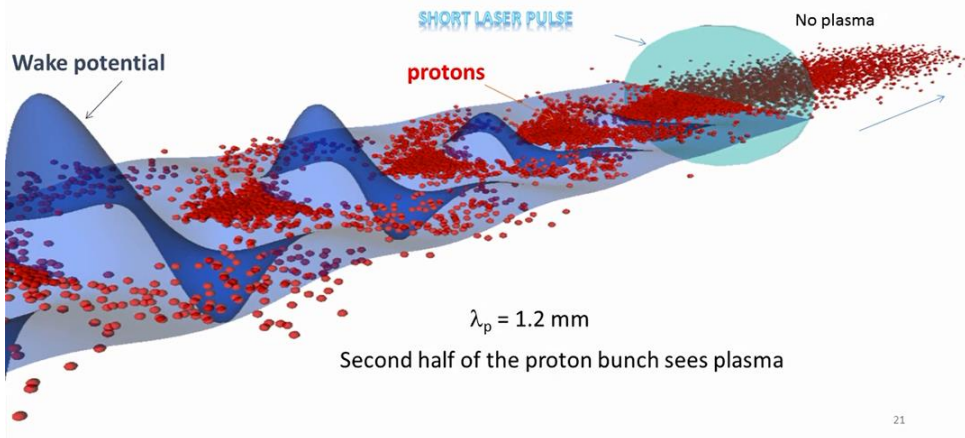

Proton bunch population $N_b$	$3 \cdot 10^{11}$
Proton bunch length $\sigma_z$	12 cm
Proton bunch radius $\sigma_r$	0.02 cm
Proton energy $W_b$	400 GeV
Proton bunch relative energy spread $\delta W_b/W_b$	0.35%
Proton bunch normalized emittance $\epsilon_{bn}$	3.5 mm mrad

# First experiment: Seeded Self-Modulation

## Seeded Self-Modulation Instability of a Long Proton Bunch in Plasma
