

Rotations for Deformed Shapes

The pure liquid drop model has a stable equilibrium only for spherical surfaces. As a consequence of quantum mechanics - i.e. shell effects - it can happen that the nucleus has a permanent deformation. We shall restrict ourselves to **axial symmetric deformations** of an even-mass nucleus (see fig. 1) which should also be invariant with respect to a rotation of 180° about the 2-axis. In this case the nucleus can only rotate around an axis perpendicular to the symmetry axis.

Figure 1: Energy spectrum (left) and shape (right) of an axial symmetric rotator.

Before we will investigate these rotations, we have to parametrize the deformed nuclear surface. One possibility is

$$R = R(\theta, \phi) = R_0(1 + \beta_0 + \beta_2 Y_{20}(\theta, \phi) + \beta_4 Y_{40}(\theta, \phi) + \dots) \quad (1)$$

where R_0 is the radius of the sphere with the same volume and $Y_{\lambda 0}(\theta, \phi)$ are the spherical harmonics. The expansion (Eq. 1) contains only even values of λ , with β_2 and β_4 being the quadrupole and hexadecapole deformation parameters, respectively. Since we require that the nuclear volume is kept fixed for all deformations, we get

$$\beta_0 = -\frac{1}{4\pi}(|\beta_2|^2 + |\beta_4|^2 + \dots) \quad (2)$$

The rotational spectrum is given by

$$E_I = \frac{\hbar^2}{2\mathcal{J}}I(I + 1) + E_{K=0} \quad (3)$$

with the band head $E_{K=0}$ and the moment of inertia \mathcal{J} . If we consider the motion of an irrotational liquid that is held in a nonspherical shape, which is rotated uniformly, the moment of inertia is given by

$$\mathcal{J}_{irr} = \frac{9}{8\pi}AMR_0^2(\beta_2^2 + \frac{5}{3}\beta_4^2) \quad (4)$$

It differs from the moment of inertia of a rigid body with the same deformation

$$\mathcal{J}_{rig} = \frac{2}{5} AMR_0^2 (1 + \sqrt{\frac{5}{16\pi}}\beta_2 + \sqrt{\frac{9}{16\pi}}\beta_4) \quad (5)$$

For the reduced transition matrix elements (Eq. ??) to the first excited states we find

$$\langle 2^+ || M(E2) || 0^+ \rangle = \sqrt{\frac{5}{16\pi}} Q_{20} e \quad (6)$$

and

$$\langle 4^+ || M(E4) || 0^+ \rangle = \sqrt{\frac{9}{16\pi}} Q_{40} e \quad (7)$$

where the intrinsic quadrupole moment Q_{20} and intrinsic hexadecapole moment Q_{40} is calculated for a uniform charge distribution in the liquid-drop model up to second order

$$Q_{20} = \frac{3ZR_0^2}{\sqrt{5\pi}} (\beta_2 + 0.360\beta_2^2 + 0.967\beta_2\beta_4 + 0.328\beta_4^2) \quad (8)$$

and

$$Q_{40} = \frac{ZR_0^4}{\sqrt{\pi}} (\beta_4 + 0.411\beta_4^2 + 0.983\beta_2\beta_4 + 0.725\beta_2^2) \quad (9)$$

Energy-B(E2) Product In the irrotational flow model the energy-B(E2) product for a pure quadrupole deformation is given by

$$E_{2^+} B(E2; 2^+ \rightarrow 0^+) = \frac{1}{5} \left(\frac{3ZeR^2}{4\pi} \right)^2 \beta_2^2 \frac{\hbar^2}{2\mathcal{J}_{irr}} 6 \quad (10)$$

with

$$\mathcal{J}_{irr} = \frac{9}{8\pi} AMR_0^2 \beta_2^2 \quad (11)$$

Thus, we get for the rotational energy-B(E2) product,

$$E_{2^+} B(E2; 2^+ \rightarrow 0^+) = 5.75 \cdot 10^{-4} \frac{Z^2}{A^{1/3}} \text{ MeV } e^2 \text{ barn}^2 \quad (12)$$

which is a factor of 2.5 smaller than the vibrational energy-B(E2) product (Eq. ??). However, the experimental product of the energy and B(E2)-value reaches only 17-19% of the rotational limit.

For the other intraband E2-transitions we find

$$\langle I+2, K=0 || M(E2) || I, K=0 \rangle = \sqrt{\frac{3(I+2)(I+1)}{2(2I+3)}} \sqrt{\frac{5}{16\pi}} Q_{20} e \quad (13)$$

$$\langle I, K = 0 || M(E2) || I, K = 0 \rangle = -\sqrt{\frac{I(I+1)(2I+1)}{(2I-1)(2I+3)}} \sqrt{\frac{5}{16\pi}} Q_{20} e \quad (14)$$

$$\langle I-2, K = 0 || M(E2) || I, K = 0 \rangle = \sqrt{\frac{3I(I-1)}{2(2I-1)}} \sqrt{\frac{5}{16\pi}} Q_{20} e \quad (15)$$

For the static M1 and E2 moments we obtain

$$\mu(I) = g_R \mu_N I \quad (16)$$

$$Q(I) = -\frac{I(I+1)}{(I+1)(2I+3)} Q_{20} \quad (17)$$

The quantity g_R is the effective g-factor for the collective motion; it is again expected to be of the order of $g_R \sim Z/A$ ($\mu_N = \frac{e\hbar}{2Mc}$).
